#### Presidential election undecided voters, 2004 - 2016

**Figure 1:** Mean level of undecided voters from US presidential elections. Weighted average from national polls that occur within a two-week window centred at x.

#### Polling error and undecided voters

**Figure 2:** State-level mean absolute error versus mean undecided voters. Polls within 35 days of elections. "Close margin" categorises state-level elections with absolute margin  $\leq$  6%.

# How do we assess state-level polling error?

## A multilevel model for polling error<sup>1</sup>

$$y_{i} \sim \mathcal{N}(p_{i}, \sigma_{i}^{2})$$

$$\log \operatorname{ic}(p_{i}) = \operatorname{logit}(v_{r[i]}) + \alpha_{1r[i]} + t_{i}\beta_{1r[i]}$$

$$\sigma_{i}^{2} = \frac{p_{i}(1 - p_{i})}{n_{i}} + \tau_{1r[i]}^{2}$$

$$(1)$$

- r[i] indexes poll i to state-year r
- $v_r$  is the actual poll result in state-year r
- $\alpha_{1r} + t_i \beta_{1r}$  time varying bias away from truth (election result)
- t<sub>i</sub> is time until election day
- $au_{1r}^2$  accounts for the excess variance above a SRS

# How do we incorporate undecided voters?

## Standardising polls and undecided voters

Standard to assume proportional allocation of undecided voters by

$$p_i = \frac{R_i}{R_i + D_i} \tag{2}$$

however you may include undecideds by letting

$$p_i' = \frac{R_i + \lambda U_i}{R_i + D_i + U_i} \tag{3}$$

where  $0 \le \lambda \le 1$  allocates the undecided voters. The values  $p_i$  and  $p_i'$  coincide under the assumption of static proportionate allocation:

$$\lambda = \frac{R_i}{R_i + D_i} \tag{4}$$

#### Incorporating undecided voters into the model

We would like to include uncertainty in undecided allocations. Assuming there is some bias away from proportionate splitting

$$\lambda = \frac{R_i}{R_i + D_i} + \theta_i \tag{5}$$

leads to the identity

$$p_i' = p_i + u_i \theta_i \tag{6}$$

which can be incorporated into the mean of the original model...

#### Incorporating undecided voters

#### ...but, there several issues:

- 1. Undecided voter levels are time-varying
- 2. Undecided voters are not reported in  $\approx 10\%$  of polls
- Undecided voter levels are themselves poll estimates ⇒
  measurement error
- 4.  $\theta_i$  is a parameter for every poll

#### Incorporating undecided voters

Model the undecided voters with

$$u_i \sim \mathcal{N}\left(\alpha_{2r[i]} + t_i \beta_{2r[i]}, \tau_{2r[i]}^2\right) \tag{7}$$

- $\alpha_{2r}$  is the the election day mean for each state-year
- Polls that don't include u<sub>i</sub> are accounted for since we estimate (and use) the state-year parameters

Addresses time varying, missing data, and measurement error concerns by using state-year estimates of undecided voters on election day.

## A model with undecided voters (and house effects)

$$y_{i} \sim \mathcal{N}(p_{i}, \sigma_{i}^{2})$$

$$\log \operatorname{ic}(p_{i}) = \operatorname{logit}(v_{r[i]}) + \alpha_{1r[i]} + t_{i}\beta_{1r[i]} - \alpha_{2r[i]}\gamma_{g[i]} + \kappa_{h[i]} \qquad (8)$$

$$\sigma_{i}^{2} = \frac{p_{i}(1 - p_{i})}{n_{i}} + \tau_{1r[i]}^{2}$$

- $\alpha_{2r}$  is the election day estimate of undecided voters for each state-year (estimated by (7) concurrently)
- $\gamma_g$  controls the amount of biasing effect from undecided voters in each election-year×result-margin g
- $\kappa_h$  is the house-effect from polling firm (or conglomerate) h

#### **Data sources**

- State level polling data
  - 2012, 2016 from Pollster API<sup>2</sup>
  - 2004, 2008 from US Election Atlas<sup>3</sup>
- Polls up to 35 days prior to their respective election included
- 2,044 state-level polls total ( $\approx$  90% had undecideds reported)
- No 2000 or earlier polls with sufficient data on undecided voters were found.

<sup>&</sup>lt;sup>2</sup>Huffington Post, *Pollster API V2*,

## So what did we find?

#### Model estimates - sources of error

**Table 1:** Average election-level absolute bias and average election-level standard deviation across state-elections in given year(s) from model (8) with assumption of proportional allocation of undecided voters.

	2004	2008	2012	2016	Overall 2004–2016
Average absolute bias	0.8% (0.11)	1.0% (0.10)	1.3% (0.10)	2.6% (0.10)	1.7% (0.06)
Average absolute election day bias	0.8% (0.12)	0.9% (0.11)	1.3% (0.14)	2.4% (0.12)	1.6% (0.07)
Average absolute undecided voter bias	0.3% (0.17)	0.4% (0.17)	1.0% (0.29)	2.1% (0.25)	1.1% (0.11)
Average absolute house effects	0.6% (0.15)	0.4% (0.12)	0.2% (0.08)	0.2% (0.09)	0.3% (0.09)
Average standard deviation	2.2% (0.04)	2.2% (0.04)	2.1% (0.04)	2.4% (0.05)	2.2% (0.03)
Average election day undecided	3.3% (0.24)	3.8% (0.21)	3.0% (0.21)	5.5% (0.28)	4.2% (0.14)

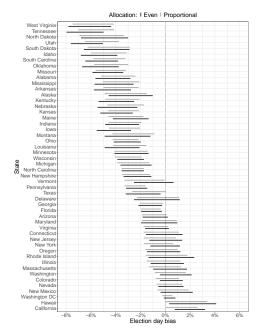

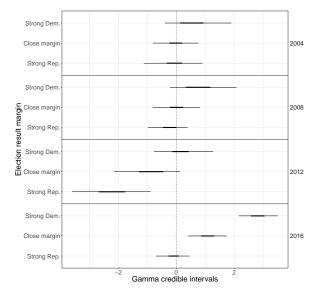

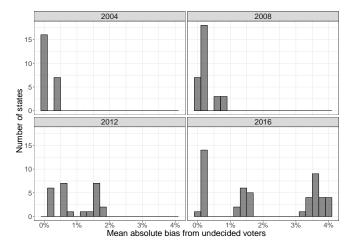

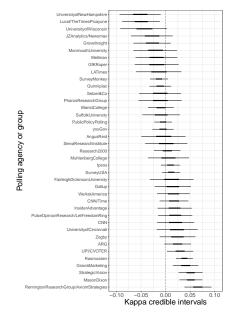

Figure 3: 95% Credible intervals for state election day bias (2016).

**Figure 4:** 95% and 50% credible intervals for  $\gamma_g$  on logit scale. A positive value indicates a bias away from proportional allocation of undecided voters in favour of the Republican candidate.

**Figure 5:** Histograms of the average absolute bias from undecided voters for each state-level election, separated by year. The bias from undecided voters is the quantity  $\alpha_{2r}\gamma_g$  in the model. A positive value indicates a bias away from proportional allocation of undecided voters in favour of either candidate.

**Figure 6:** 95% (outer line) and 50% credible intervals for house effects bias from polling organisations in the model  $(\kappa_h)$ , on the logit scale

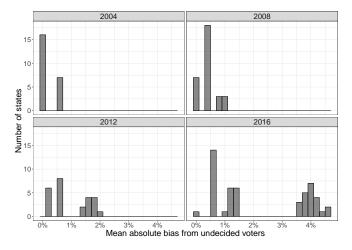

#### **Concluding remarks**

- In 2016, 5.5% of voters were undecided on election day, up from 3.0–3.8% in previous years
- Undecided voters biased polls in the 2016 US presidential election by 2.1 percentage points on average
- A static, proportionate split in undecided voters between leading candidates was a bad assumption in 2016, less so in previous years
- Pollsters and modellers should move towards stochastic allocation methods to allow uncertainty from undecided voters to propagate through models

## **Appendix**

Table 2: Priors used in models for analysis of state polls.

		Prior	Hyper-prior		
Model	Component		Mean	Variance	
		$\alpha_{1r} \sim \mathcal{N}(\mu_{1\alpha}, \sigma_{1\alpha}^2)$	$\mu_{1lpha} \sim \mathcal{N}(0, 0.2)$	$\sigma_{1lpha} \sim \mathcal{N}_+(0,0.2)$	
Polling	Mean	$eta_{1r} \sim \mathcal{N}(\mu_{1eta}, \sigma_{1eta}^2)$	$\mu_{1eta} \sim \mathcal{N}(0, 0.2)$	$\sigma_{1eta} \sim \mathcal{N}_+(0,0.2)$	
		$\gamma_{m{g}} \sim \mathcal{L}(0, 0.05)$			
		$\kappa_{h} \sim \mathcal{N}(\mu_{\kappa}, \sigma_{\kappa}^{2})$	$\mu_{\kappa} \sim \mathcal{N}(0, 0.05)$	$\sigma_{\kappa} \sim \exp(1/0.05)$	
	Variance	$ au_{1r}^2 \sim \mathcal{N}_+(0,\sigma_{1 au}^2)$		$\sigma_{1 au} \sim \mathcal{N}_+(0, 0.05)$	
		$lpha_{2r} \sim \mathcal{N}(\phi_{ ext{virl}}, \sigma_{2lpha}^2)$	$\phi_{ m v} \sim \mathcal{N}(0.04, 0.01)$	$\sigma_{2lpha} \sim \mathcal{N}_+(0,0.02)$	
Undecided voters	Mean	$\beta_{2r} \sim \mathcal{N}(\mu_{2\beta}, \sigma_{2\beta}^2)$	$\mu_{2eta} \sim \mathcal{N}(0, 0.02)$	$\sigma_{2eta} \sim \mathcal{N}_+(0,0.02)$	
	Variance	$ au_{2r}^2 \sim \mathcal{N}_+(0,\sigma_{2 au}^2)$		$\sigma_{2 au} \sim \mathcal{N}_+(0,0.01)$	

**Figure 7:** Histograms of the average absolute bias from undecided voters for each state-level election, separated by year. The bias from undecided voters is the quantity  $\alpha_{2r}\gamma_g$  in the model. A positive value indicates a bias away from 50/50 allocation of undecided voters in favour of either candidate.

**Table 3:** Average house effects across elections. Only those polling agencies with absolute mean posterior greater than 0.5% are shown.

	Posterior
